In a cooling system of this type there is a continual slight loss of coolant if the engine runs very hot. The system needs topping up from time to time. Later cars have a sealed system in which any overflow goes into an expansion tank, from which it is sucked back into the engine when the remaining liquid cools.

gasoline engines have improved a lot, they are still not very efficient at turning chemical energy into mechanical power. 2. Most of the energy in the gasoline (perhaps 70%) is converted into heat, and it is the job of the cooling system to take care of that heat.

The cooling system in your vehicle is designed to keep the engine at a consistent temperature. It keeps the engine from running too hot or too cold once it is warmed up. The cooling system consists of several main components that each perform a different task.
